RE: The use of Fossil Shell Flour in our veterinary practice

Dear Wally,

FSF is given free choice to calves at 36 to 48 hours after birth. The calves readily consume it, even at this young age. In a very few cases FSF is placed in the mouth so that they acquire a taste for it. Following this they eat it on their own.

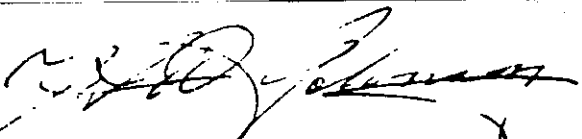

FSF has been used on approximately 2,000 calves; the results have been consistent and gratifying. The incidence of calf scours has been 99% eliminated. There have been cases of Diarrhea, but this has been due to the calf over eating on milk. No true case of calf scours as such has been observed.

The reason for FSF doing such a commendable job of preventing calf scours, pneumonia and white muscle disease is due to the baby being provided with a well-balanced complex of chelated minerals. Dr. Carey Reams, a respected Bio-physicist, held the view that practically all diseases were caused by a mineral deficiency and/or imbalance in the body.

Our experience in our own herd of beef cattle has been that by using FSF we have been able to stop the use of vaccines and antibiotics.

We also have abandoned the use of herbicides, pesticides and commercial fertilizers. All of the above practices have accomplished two things in our operation: 1. Healthier cattle and, 2. A financially viable enterprise.

Best Regards,

(H. D. JOHNSON) D.V.M.
